

Non-Technical Summary (100 Words)

The security assessment revealed several weaknesses that could allow attackers to gain unauthorized access to the system. Issues such as insecure login mechanisms, outdated software, weak passwords, and unsafe web inputs were identified. These vulnerabilities could enable attackers to steal data, manipulate the system, or disrupt services. While the environment tested was intentionally vulnerable, the results reflect common real-world risks. Fixing these issues requires updating software, improving password policies, validating user inputs, and strengthening overall security settings. With the recommended improvements, the system will be significantly more secure and resistant to cyberattacks.
